

- Map Layer Descriptions -

<https://nzgd.org.nz>

The New Zealand Geotechnical Database presents a large quantity of geotechnical information, which is presented in a hierarchical set of information layers that can be selectively displayed. The layer hierarchy is grouped to provide rapid access to individual layers within each map layer collection. The map layers themselves are further classified either as geotechnical investigation data (both individual and collated) or as published maps and reports.

The Map Layers

Each map layer displays a description outlining the important information about the data being displayed when it is initially opened. These descriptions are collated here so they can all be printed out for reference while using a viewer.

Most map layers within the New Zealand Geotechnical Database are composed from a number of internal layers, which can be selectively switched on and off. These are usually arranged so only one internal layer is displayed at a time (e.g. for a particular earthquake). The map layers are numbered for reference purposes (e.g. CGD0100, CGD0200 etc.), but please use descriptions (e.g. 5 Sept 2010 Aerial Photography) rather than the mostly hidden reference numbers when referring to the internal layers (e.g. CGD0101, CGD0102 etc. within map layer CGD0100).

The map layer descriptions following this introduction should be clearer with an appreciation of how viewing software such as Google Earth operates. The satellite images forming the background are tiled to efficiently receive them from the server in small chunks. The tiles are also arranged as a pyramid, with the images that have the largest pixels sizes at the top level and the smallest at the bottom. The top image is viewed from long distances, or high eye altitudes, so the user can efficiently navigate toward detailed items in the lowest level pyramid level. Portions of the lower level images are progressively loaded as the eye altitude decreases (i.e. as the user *zooms in* toward the finest detailed images).

The tiling and creation of image pyramids are core procedures within the publication process for each map (or internal) layer, so are not explicitly included in the methodology outlined in the descriptions. The same tiling process was also used for large quantities of geometric shapes and groups of individual place marks.

Version control for the map layers is principally through their publication dates. While much of the data within each map layer is static, the display arrangements can change as additional data is added or improved arrangements are suggested.

This document is updated whenever one of the map layers is updated. If a copy of this document is printed, please check the release date beside the printed map title against the date within the citation instructions immediately above the Important Notice in each description (e.g. 1 June 2012 as highlighted in the sample excerpt below) as it is loaded. The revision history is summarised at the end of this document.

Cite figures or other works derived from these map layers (see the Important Notice below) as:

New Zealand Geotechnical Database (2012) "Aerial Photography", Map Layer CGD0100 - **1 June 2012**, retrieved [date] from <https://www.nzgd.org.nz/>

Important notice

This map and data was prepared and/or compiled for the Earthquake Commission (EQC) to assist in assessing insurance claims made under the Earthquake Commission Act 1993 and/or for the New Zealand Geotechnical Database on behalf of the Canterbury Earthquake Recovery Authority (CERA). It was not intended for any other purpose. EQC, CERA, their data suppliers and their engineers, Tonkin & Taylor, have no liability to any user of this map and data or for the consequences of any person relying on them in any way. Each New Zealand Geotechnical Database map and data is made available solely on the basis that:

- Any database user has read and agrees to the terms of use for the database;
- Any database user has read any explanatory text accompanying this map;
- The "Important notice" in the following box must be reproduced in a prominent location with an appropriate substitution to the red bracketed text (i.e. within the []) wherever the map, data or derivative figures or tables are reproduced.

Important notice

[Figures X, Y and Z were] created from maps and/or data extracted from the New Zealand Geotechnical Database (<https://www.nzgd.org.nz>) which were prepared and/or compiled for the Earthquake Commission (EQC) to assist in assessing insurance claims made under the Earthquake Commission Act 1993 and/or for the Canterbury Earthquake Recovery Authority (CERA). The source maps and data were not intended for any other purpose. EQC, CERA, their data suppliers and their engineers, Tonkin & Taylor, have no liability for any use of the maps and data or for the consequences of any person relying on them in any way. This "Important notice" must be reproduced wherever [those three figures] or any derivatives are reproduced.

Using the Map Layers

Simultaneously overlay combinations of map layers and internal layers to synthesise an understanding of the physical meaning of the information being displayed. This is also helpful for both identifying and quantifying the noise or error within the acquired data.

A lot of the data is colour banded and/or contoured for presentation, with the bands of constant colour between contours. Jagged band boundaries (or contours) provide good indicators of the amount of noise within the information being displayed. The colour bands are often rendered as bitmap images rather than vector shapes and lines because of the quantity of information being presented. This conveniently also provides fuzzy boundary when the user zooms in to view the information more closely than the data warrants.

Some viewing software provides terrain exaggeration and background imagery with unspecified location accuracy, which can affect the apparent positions of features. Users may need to independently verify positions when using low viewing elevations. The aerial photography layer (CGD0100), particularly the high resolution 24 Feb 2011 layer, can provide better background imagery for Christchurch.

Finally, the database is frequently updated. It is therefore essential to view newly added data and avoid using superseded data by restarting the viewing software occasionally (e.g. at least daily) to refresh the internal cache.

Map Layer and Description	Reference	
<p>For the SLS, ILS and ULS design scenario earthquakes, indicators are mapped for 15th percentile, median and 85th percentile groundwater surface elevations. Only the depth to groundwater is spatially varied, based on the GNS Science Median Water Table Elevations (Map Layer CGD5160) and the most recent (Feb 2012 augmented with Sept 2011) DEM. These maps allow designers to investigate how these influence the local variation of each vulnerability indicator.</p> <p>Regional-scale maps</p> <p>These regional-scale maps of the liquefaction vulnerability indicators are provided for information purposes only and do not remove the obligation for designers to conduct site specific assessments and analyses. The technical specification describes the indicator calculations. Of particular note for the regional analysis maps:</p> <ul style="list-style-type: none"> • Soil properties were estimated for any pre-drill material removed from CPT sites. • The seismic loading was based either on probabilistic adjustment to an empirical ground motion model at recording station sites or on a standard PGA and magnitude earthquake; • The groundwater conditions used either the event-specific or probabilistic regional groundwater models. • Sites were assumed to be both flat and laterally confined (i.e. no sloping ground surface or lateral spreading). • Only the top 10 m was analysed for consistency between indicators. <p>Site specific analyses</p> <p>Site specific analyses should consider the following aspects that were not explicitly incorporated in the regional analysis:</p> <ul style="list-style-type: none"> • Soil susceptibility assessments and appropriate I_c cut-off profiles based on laboratory test results. • Specific finer content profiles based on laboratory test results. • Site specific material investigations for the CPT investigations that had material removed above the groundwater table (pre-drill). • Thin layer corrections to the CPT traces. • Local variations in site topography, either existing or proposed, when the site is not flat; • Lateral confinement that is insufficient to limit or prevent lateral spreading. <p>References</p> <p>Tonkin and Taylor (2013) Liquefaction vulnerability study, Tonkin and Taylor Report 52020.0200. Map Layer and Description	Reference	
CPT Layer Analysis and Depth of Refusal	CGD0055	
<p>Description</p> <p>Depth to the upper surface of the first hard layer and the depth to refusal detected in a CPT profile, relative to the ground surface.</p> <p>Methodology</p> <p>This investigation analysis tool is applied to all of the CPT profiles checked in to the Geotechnical Investigation Data portion of the New Zealand Geotechnical Database.</p> <p>Hard layers are those with 90% of the recorded qc greater than 20 MPa, over a selectable layer thickness of 0.1 m to 0.5 m. The hard layer suggesting refusal is where the recorded qc is greater than 20 MPa, over the selectable layer thickness. These maps only show depths for CPT profiles that have an identifiable hard layer of the nominated thickness.</p> <p>As this is an automated analysis tool, this map layer should only be used to estimate effective refusal depths when planning a new site investigation based on other investigations within the general area. The original CPT investigation data should be evaluated manually for all other purposes.</p> <p>Cite figures or other works derived from these map layers (see the Important Notice, Page 3) as: New Zealand Geotechnical Database ([enter year]) "CPT Layer Analysis and Depth of Refusal", Map Layer CGD0055, retrieved [enter date] from https://www.nzgd.org.nz/</p>

Soil Behaviour Type Index (<i>I_c</i>)	CGD0060	
<p>Description</p> <p>Maps of the averaged Soil Behaviour Type Index (<i>I_c</i>) for 1 m thick slices of CPT profiles.</p> <p>Methodology</p> <p>This investigation analysis tool, based on Robertson & Wride (1998) and Youd et al. (2001), is applied to all of the CPT profiles uploaded to the Geotechnical Investigation Data portion of the New Zealand Geotechnical Database. The tool is only run fortnightly, so new CPT profiles may be mapped up to a fortnight after they are checked in.</p> <p>The soil behaviour type index (<i>I_c</i>), with normalised tip resistance and sleeve friction for the CPT cone, indicates whether the soil behaves as a coarse grained or fine grained soil. This is calculated for each CPT profile using the Robertson & Wride (1998) method as outlined in CGD Technical Specification 01 (2013), averaged over 1 m thick slices and classified for each slice between 0 and 10 m deep within the CPT profile.</p> <p>As this is an automated analysis tool, this map layer should only be used to estimate the Soil Behaviour Type Index when planning a new site investigation based on other investigations within the general area. The original CPT investigation data should be evaluated manually for all other purposes.</p> <p>References</p> <p>Robertson, P.K. & Wride, C.E., (1998). <i>Evaluating cyclic liquefaction potential using the cone penetration test</i>, Canadian Geotechnical Journal, 35:442 – 459</p> <p>Youd, T.L., Idriss, I.M., Andrus, R.D., Arango, I., Castro, G., Christian, J.T., Dobry, R., Finn, W.D.L., Harder Jr., L.H., Hynes, M.E., Ishihara, K., Koester, J.P., Liao, S.S.C, Marcuson, W.F., Marting, G.R., Mitchell, J.K., Moriwaki, Y., Power, M.S., Robertson, P.K., Seed, R.B, & Stokoe, K.H. Liquefaction Interpreted from Aerial Photography	CGD0200	11 Feb 2013

Description

A regional-scale map showing the extents of ejected liquefaction material interpreted from aerial photography

Methodology

The quantity of ejected liquefaction material deposited on the streets was visually identified using the aerial photographs. Aerial photographs taken after each of the significant earthquakes were examined using Google Earth. Regions of the city with visible evidence of ejected material were identified and digitized. The region boundaries were aligned with road centre-lines and property boundaries rather than the boundaries of the individual surface features being mapped.

Classification	Apparent Features
MODERATE to SEVERE	<ul style="list-style-type: none"> • Roads had either ejected material or wet patches wider than a typical vehicle width • Ejected material in grass or on roads • Groups of 2-3 ejected material 'boils' within properties or parks
MINOR	<ul style="list-style-type: none"> • Roads had either ejected material or wet patches narrower than a typical vehicle • Only one or two ejected material 'boils' within a property or park
NONE	<ul style="list-style-type: none"> • None of the above features were observed

The photographs were of varying quality and light conditions. Shadows from low sun angles in some areas and sets of photographs may have been misidentified as ejected liquefaction material. Water from burst pipes or springs could also be misidentified as ejected material. Conversely, ejected material may have been obscured from view or removed before the photographs were taken. Photographs were not available for all areas of the city and there were no observations in the Port Hills.

These maps should be used in conjunction with the associated Aerial Photograph and property-scale observations to form a complete picture of the extent and severity of the liquefaction.

Liquefaction and Lateral Spreading Observations	CGD0300	11 Feb 2013
<p>Description</p> <p>Property or road scale maps showing categorised quantities of ejected material and lateral spreading observed after the 4 Sept 2010, 22 Feb 2011 and 13 June 2011 Earthquakes</p> <p>Methodology</p> <p>The quantities of material ejected due to liquefaction and observations of lateral spreading were collated from on-foot rapid inspection of individual properties following each significant earthquake. The observations were categorized according to the quantity of ejected material observed on the ground surface and according to the presence or absence of evidence of lateral spreading. Each of these three categories was further subdivided according to the severity.</p> <p>The observations were collected for the Earthquake Commission and were only made in residential areas. The mapping only identified liquefaction and lateral spreading that was visible at the surface at the time of inspection. Liquefaction may have occurred at depth without obvious evidence at the surface and evidence of liquefaction may have been removed before the inspection. (Removed material may be identifiable within the aerial photographs that were taken within a day or two of the earthquake.)</p> <p>The properties were not all inspected between each pair of consecutive earthquakes (e.g. between 4 Sept 2010 and 22 Feb 2011) so the extent of the land deformations is most likely incomplete. Also, some observations following the 22 Feb 2011 and 13 Jun 2011 earthquakes could have been induced by preceding earthquakes.</p> <p>Cite figures or other works derived from these map layers (see the Important Notice, Page 3) as: New Zealand Geotechnical Database (2013) "Liquefaction and Lateral Spreading Observations", Map Layer CGD0300 - 11 Feb 2013, retrieved [date] from) from https://www.nzgd.org.nz/</p> <p>Revisions</p> <p>01 Oct 2012 – Initial release 11 Feb 2013 – Added Road Observations map for 22 Feb 2011 earthquake 22 Sep 2016 – Added street mapped and photo observations for 14 Feb 2016 earthquake</p>

Observed Ground Crack Locations	CGD0400	23 July 2012
<p>Description</p> <p>Digitized Ground Crack Locations following the 4 Sept 2010 and 22 Feb 2011 Earthquakes</p> <p>Methodology</p> <p>Crack locations were mapped in order to infer the general direction, magnitude and extent of the lateral spreading. Field observations of crack locations were recorded using coloured pens on paper copies of aerial photographs. The marked-up photographs were later scanned and the coordinates of the coloured lines were manually digitized.</p> <p>The mapping objectives changed in response to the varying situation following the two earthquakes. Observations after the 4 Sept 2010 Earthquake were principally for insurance claim settlements. The crack widths were recorded in property-by-property observations, but cracks were not tracked across property boundaries and only a portion of properties were mapped before the 22 Feb 2011 Earthquake.</p> <p>Cracks were mapped at a scale of 1:5000 to 1:10000 for about two weeks following the 22 Feb 2011 Earthquake in order to rapidly identify the extent of lateral spreading following the earthquake. The individual crack widths were not recorded.</p> <p>From early March 2011, cracks were generally mapped at a scale of 1:2000 and classified according to their maximum width (with many tapering to nothing at both ends). Cracks were tracked through properties in order to identify spreading regions rather than spreading within individual properties.</p> <p>The crack mapping is incomplete and only observations made by the mapping teams are presented. In particular, the mapping following the 4 Sept 2010 Earthquake was incomplete before the 22 Feb 2011 Earthquake occurred and subsequent mapping remains incomplete within the residential 'red zone' areas. Also, cracks in roads were often not able to be mapped because many were filled and the roads resealed before a mapping team arrived.</p> <p>The suggested viewing scale for this map is 1:3000, which is a viewing altitude of about 1 km in Google Earth. All crack locations include unquantified errors in the orthorectified aerial photographs (see Aerial Photographs map layer notes), the manual field recording method, the photograph printing and scanning equipment, manual digitization and dimensional changes within the paper.</p> <p>Colours for the 50 to 200 mm crack widths are similar for both sets of data to provide an overview of the spreading rather than to provide a comparison between earthquakes. (The colours can be changed by the user if required.)</p> <p>Cite figures or other works derived from these map layers (see the Important Notice, Page 3) as: New Zealand Geotechnical Database (2012) "Observed Ground Crack Locations", Map Layer CGD0400 - 23 July 2012, retrieved [date] from https://nzgd.org.nz</p>

LiDAR and Digital Elevation Models	CGD0500	30 June 2015

Description

Pre and post earthquake Digital Elevation Models (DEM) created from Airborne LiDAR

Methodology

LiDAR was acquired by AAM Brisbane (AAM) and New Zealand Aerial Mapping (NZAM) following each of the significant earthquakes. The suppliers classified the acquired points allowing the creation of a bare earth or terrain model, by removing points for structures and vegetation that were judged to be higher than 0.5 m above the surrounding ground. A DEM was developed from each supplied LiDAR set by averaging the ground-return elevations within a 10 m radius of each grid point. All of these DEM's used a common 5 m grid and used either moving averages or windowed averages. Each DEM was colour banded and rendered in an image pyramid to create a viewable version of the underlying elevation model. Colours were clipped from the images around significant waterways and coastal marine areas.

The LiDAR sources and commissioning agencies for each Digital Elevation Model are tabulated below:

DEM	Source LiDAR	Commissioning Agencies
Pre-Earthquake	AAM, 6-9 Jul 2003* AAM, 21-24 Jul 2005	Christchurch City Council Environment Canterbury & Waimakariri District Council
Post-Sept 2010	AAM, 6-11 Feb 2008 NZAM, 5 Sep 2010	Environment Canterbury & Selwyn District Council Ministry of Civil Defence and Emergency Management
Post-Feb 2011	NZAM, 8-10 Mar 2011 AAM, 20-30 May 2011	Ministry of Civil Defence and Emergency Management Christchurch City Council
Post-June 2011	NZAM, 18 & 20 Jul, 11 Aug, 25-27 Aug, and 2-3 Sept 2011	The Earthquake Commission
Post-Dec 2011	NZAM, 17-18 Feb 2012	The Earthquake Commission

The NZAM LiDAR was acquired using instruments and procedures that give a fundamental vertical accuracy of ±0.10 m (one sigma) for areas of open ground with hard surfaces. The accuracy is in terms of a reference network defined by field surveying data. Metadata for the AAM LiDAR indicates a vertical accuracy of ±0.07 to ±0.15 m (excluding GPS error and Geoid modelling error) and 0.40 to 0.55 m horizontal.

The pre-earthquake LiDAR has lower accuracy and sparser LiDAR point sets than the post-earthquake sets. The post-Feb 2011 DEM was created from two partially overlapping LiDAR sets, with points taken from the more accurate 20-30 May set in preference to the 8-10 Mar set wherever the two sets overlapped.

The vertical elevations were calibrated against land-based survey data supplied by the Christchurch City Council, Land Information New Zealand and Environment Canterbury from surveys of their benchmark networks. All of the LiDAR elevation measurement points within a 1 m radius of each benchmark were extracted from each of the point clouds. The elevation difference between each measurement point and its adjacent benchmark were incorporated in a separate

Map Layer and Description	Reference	Published
<p>layer. The accuracy of the supplied survey data was not quantified. Statistics for calibration of the LiDAR point cloud sets are:</p>

<p>Vertical Ground Surface Movements</p>	<p>CGD0600</p>	<p>23 July 2012</p>
<p>Description</p> <p>Vertical elevation changes between LiDAR sets that approximate the vertical ground movements during significant earthquakes</p> <p>Methodology</p> <p>Elevation changes were calculated both for individual earthquakes (and their associated aftershocks) and for sets of consecutive earthquakes as differences between pairs of Digital Elevation Models (DEM). These 'observed' elevation differences for the overlapping region of each DEM pair were colour banded and rendered in an image pyramid. Colours were clipped from the images around significant waterways and coastal marine areas.</p> <p>GNS Science dislocation models of the vertical tectonic movements during each earthquake were also colour banded for a separate layer. The vertical movements were summed for sets of consecutive earthquakes and presented in other layers. Contours of the tectonic movements are also provided as overlays for other maps.</p> <p>Local vertical movements were calculated as the differences between the 'observed' elevation differences and the associated tectonic models. These are presented as a third layer for each event combination.</p> <p>All of the movements are differences between DEMs and are inherently less accurate than their source DEM's. The pre-earthquake source DEM is less accurate than the post-earthquake DEMs (see notes accompanying the LiDAR and Digital Elevation Models map layers), so all four sets of movements derived from that DEM have more error than the other difference sets. The post-Feb 2011 DEM was created from two partially overlapping LiDAR sets, with points taken from the more accurate set wherever the two sets overlapped. Some of the DEMs have visually distinguishable lines or ripples within the colour bands that are almost certainly artefacts from the data acquisition and subsequent processing rather than from physical vertical movements. Notable examples are several approximately NNE-SSW swathes visible in the Feb 2011 difference set and an almost E-W line at 43.48°S in the 13 Jun 2011 difference set.</p> <p>The earthquake dates are abbreviated as S10, F11, J11 and D11 in the Google Earth sidebar (for 4 Sept 2010, 22 Feb 2011, 13 June 2011 and 23 Dec 2011 respectively). The time interval for each difference set is displayed graphically in the sidebar, using an "X" beneath the earthquake label for one earthquake and ">---<" for cumulative movements during two or more earthquakes.</p> <p>Cite figures or other works derived from these map layers (see the Important Notice , Page 3) as: New Zealand Geotechnical Database (2012) "Vertical Ground Surface Movements", Map Layer CGD0600 - 23 July 2012, retrieved [date] from https://www.nzgd.org.nz/</p>

Horizontal Ground Surface Movements	CGD0700	23 July 2012
<p>Description</p> <p>Horizontal ground surface movements between LiDAR sets that approximate the movements during significant earthquakes</p> <p>Methodology</p> <p>Horizontal movements were calculated for both individual earthquakes (and their associated aftershocks) and sets of consecutive earthquakes as differences between pairs of LiDAR point clouds. The horizontal movements for each earthquake combination were calculated using a sub-pixel correlation method developed by Imagin' Labs Corporation and California Institute of Technology. The movements were calculated on 4 m grids (8 m for the pre-earthquake LiDAR sets) from both ground and non-ground LiDAR points and averaged to provide Cartesian movements in a 56 m grid. The averaging distance was tailored to the noise in the two LiDAR sets.</p> <p>The horizontal movements were rendered as arrows on a 56 m grid to indicate both direction and magnitude of the movement at each grid point. The arrows were scaled 56:1 so an arrow between two adjacent grid points (e.g. east-west or north-south) represents 1.0 m movement in the indicated direction. Arrows were not plotted in significant waterways, coastal marine areas and most other non-residential land where the movements were poorly correlated and produced less accurate horizontal movement estimates. The correlation process and horizontal movements are also significantly affected by elevation errors. Some of the horizontal movement are also influenced by localised changes such as new or demolished buildings, vegetation and earthworks for subdivisions.</p> <p>GNS Science dislocation models of the horizontal tectonic movements during each earthquake were also colour banded and presented in a separate layer. The horizontal movements were summed for sets of consecutive earthquakes and presented in other layers. Contours of the tectonic movements are also provided as overlays for other maps.</p> <p>"Local" horizontal deformations were calculated as the differences between the 'observed' movements and the associated tectonic models. These are presented as a third layer for each event combination.</p> <p>The pre-earthquake source DEM is less accurate than the post-earthquake DEMs (see notes accompanying the LiDAR and Digital Elevation Models section) so all four sets of movements derived from that DEM have more error than the other difference sets. The post-Feb 2011 DEM was created from two partially overlapping LiDAR sets, with points taken from the more accurate set wherever the two sets overlapped.</p> <p>The horizontal movements were calibrated against data supplied by the Christchurch City Council, Land Information New Zealand and Environment Canterbury from surveys of their benchmark networks. The horizontal movements at the benchmark locations are presented in a separate layer.</p> <p>The earthquake dates are abbreviated as S10, F11, J11 and D11 in the Google Earth sidebar (for 4 Sept 2010, 22 Feb 2011, 13 June 2011 and 23 Dec 2011 respectively). The time interval for each difference set is displayed graphically in the sidebar, using an "X" beneath the earthquake label for one earthquake and ">---<" for cumulative movements during two or more earthquakes.</p>

Event Specific Groundwater Surface Elevations	CGD0800	12 June 2014
<p>Description</p> <p>Groundwater surface elevations based on Environment Canterbury (ECan) and Tonkin & Taylor Ltd (T&T) measurements</p> <p>Methodology</p> <p>Water level dip measurements from wells installed for the Earthquake Commission (EQC) and ECan since Sept 2010 were used to augment measurements from existing shallow wells supplied by ECan. Water level dips were converted to free surface elevations, based on surveyed well-head levels.</p> <p>Surface models were fitted to the elevations recorded at these wells and the adjacent rivers immediately prior to the 4 Sept 2010, 22 Feb 2011, 13 June 2011 and 23 Dec 2011 earthquakes. Geographically sparse well measurements for the earlier earthquakes were augmented with observations from the newly installed wells. Some predicted elevations were the elevation measured one year after the earthquake and the remainder were extrapolated back in time using the variation observed in adjacent wells. The fitted surface for each earthquake was colour banded and rendered in an image pyramid. The well locations are also plotted.</p> <p>Groundwater depths were derived from the free surface elevations prior to each earthquake by subtracting the elevations from the most appropriate LiDAR-derived digital surface elevation model. The depths were colour banded and rendered.</p> <p>The free surface elevations only provide mean values at the time of each earthquake and are only suitable for back analysis purposes. They are indicative only, with no allowance for extreme or seasonal fluctuations, or for localised perturbations (e.g. changes in topography or permeability) away from the measured well. They are not suitable for design.</p> <p>Users should note that the free surface elevations are periodically updated using elevations recorded in new well installations and longer durations of observations within existing wells, which are both extrapolated back in time as outlined above.</p> <p>The Environment Canterbury wells have links to their published ground water monitoring data.</p> <p>Reference: Tonkin & Taylor (2012) Canterbury Earthquakes 2010 and 2011 Land Report as at 29 February 2012, retrieved 26 July 2012 from http://canterbury.eqc.govt.nz/news/reports</p> <p>Cite figures or other works derived from these map layers (see the Important Notice, Page 1) as: New Zealand Geotechnical Database (2014) "Event Specific Groundwater Surface Elevations", Map Layer CGD0800 – 12 June 2014, retrieved [date] from https://www.nzgd.org.nz/</p> <p>Revisions</p> <p>01 Oct 2012 – Initial release 20 Nov 2012 – All map layers replaced to incorporate back extrapolation of new observations 11 Feb 2013 – All layers replaced (as above). Replaced maps moved to new Superseded section 12 Jun 2014 – All layers replaced to reflect Version 2 of the CGD5160 Median Surface</p>

CERA Residential Zoning Maps	CGD5010	30 Jan 2013
<p>Description</p> <p>Residential property damage zones to guide the recovery and rebuild process. First published by CERA on 23 June 2011 and updated on 5 December 2013.</p> <p>This map will be updated as new information is released.</p> <p>The damage zones are only for residential properties and specifically exclude all other property types, including schools, parks, commercial zones, and the central business district (CBD).</p> <p>Zones were initially identified from engineering assessments of residential land, building and infrastructure damage. The zone boundaries were adjusted using the criteria set by the New Zealand Government on the basis of whether it was practical to repair properties in a timely and cost effective way.</p> <p>New Zealand Geotechnical Database - Map Layer CGD5010 - 30/01/2014</p>		
MBIE Residential Foundation Technical Categories	CGD5020	30 Jan 2014
<p>Description</p> <p>The "Residential Foundation Technical Categories" map first published by the Ministry of Business, Innovation and Employment on 28 October 2011 and updated 5 December 2013.</p> <p>Technical Category 1 (TC1)</p> <p>Future land damage from liquefaction is unlikely, and ground settlements are expected to be within normally accepted tolerances. Standard foundations (NZS 3604) are acceptable subject to shallow geotechnical investigation.</p> <p>Technical Category 2 (TC2)</p> <p>Minor to moderate land damage from liquefaction is possible in future large earthquakes. Lightweight construction or enhanced foundations are likely to be required such as enhanced concrete raft foundations (ie, stiffer floor slabs that tie the structure together).</p> <p>Technical Category 3 (TC3)</p> <p>Moderate to significant land damage from liquefaction is possible in future large earthquakes. Foundation solutions should be based on site-specific geotechnical investigation and specific engineering foundation design.</p> <p>The CERA Technical Categories Map displays this map as a web service.</p> <p>The shapefiles for this map are available from the New Zealand Geospatial Services Portal or the CERA folder within the ArcGIS Services Directory.</p> <p>New Zealand Geotechnical Database - Map Layer CGD5020 - 30/01/2014</p>

Conditional PGA for Liquefaction Assessment	CGD5110	30 June 2015
<p>Description</p> <p>Conditional Peak Ground Accelerations (PGA) developed for conventional liquefaction assessments by Bradley Seismic Ltd. and the University of Canterbury</p> <p>Methodology</p> <p>Peak Ground Accelerations were estimated for the site-specific assessment of liquefaction due to significant earthquakes throughout the greater Christchurch region. The PGA at each location within the region was calculated for each earthquake by combining the prediction from an empirical ground motion model of the fault rupture with the PGA recorded at any adjacent strong motion stations. Locations far from any strong motion station were predominantly influenced by the predicted, log-normally distributed, PGA (termed unconditional) whereas those at a station were the (conditional) recorded PGA. The conditional PGA at each location is defined probabilistically in terms of its median value and its uncertainty or (lognormal) standard deviation.</p> <p>The conditional median PGA was contoured and the standard deviation was colour banded so the two can be displayed simultaneously. (Click on a median contour or uncertainty band to display its value.) Contours are also provided for the standard deviations.</p> <p>These map layers only provide median and standard deviation PGA values for each earthquake. They are only suitable for estimating the PGA at a particular location, during a historic earthquake. They are not suitable for design.</p> <p>The Ministry of Business, Innovation and Employment’s Sept 2012 <i>Guidelines for the investigation and assessment of subdivisions on the flat in Canterbury</i> suggest using these map layers to decide whether sites have been “sufficiently tested at the serviceability limit state” during recent seismic events. (see http://www.dbh.govt.nz/subdivisions-assessment-guide)</p> <p>Strong-motion station locations were extracted from the GeoNet DELTA database in 2015.</p> <p>References</p> <p>Bradley and Hughes (2012a) Conditional Peak Ground Accelerations in the Canterbury Earthquakes for Conventional Liquefaction Assessment, Technical Report for the Ministry of Business, Innovation and Employment, April 2012. 22p.</p> <p>Bradley and Hughes (2012b) Conditional Peak Ground Accelerations in the Canterbury Earthquakes for Conventional Liquefaction Assessment: Part 2, Technical Report for the Ministry of Business, Innovation and Employment, December 2012. 19p.</p> <p>GeoNet DELTA application, accessed 5 June 2015, https://magma.geonet.org.nz/delta/app</p> <p>Cite figures or other works derived from these map layers (see Important Notice, Page 3) as: New Zealand Geotechnical Database (2015) "Conditional PGA for Liquefaction Assessment", Map Layer CGD5110 – 30 June 2015, retrieved [date] from https://www.nzgd.org.nz/</p> <p>Revisions</p> <p>27 Sep 2012 – Initial release 11 Feb 2013 – All layers corrected and layers added for additional significant earthquakes 19 Feb 2013 – Revised 11 Feb 2013 corrections for 22 Feb 2011 earthquake 30 Jun 2015 – Added PGA observations at GeoNet strong-motion recording stations</p>

GNS Science Median Water Table Elevations (Version 2)	CGD5160	10 June 2014
<p>Description</p> <p>Maps of the median water table, as both elevation and depth below ground, across Christchurch City and surrounding area, representing the period since the 4 September 2010 M_w 7.1 Darfield Earthquake. These version 2 (2014) maps are based on monitoring from Sept 2010 to Nov 2013.</p> <p>Groundwater Protection Zones</p> <p>Three broad land-surface groundwater protection zones proposed by Weeber (2008) for the Christchurch-West Melton groundwater system. The zone boundaries are defined by the 3 m thickness contour of near-surface, fine-grained sediments and the boundary between the upward and downward hydraulic gradients in the shallow aquifers (Riccarton, Springston and Christchurch formations).</p> <p>This map provides an indirect outline of areas characterised by upward and downward hydraulic gradients, and places where superficial fine-grained deposits that act as aquifer confining layers in the Eastern/Coastal Zone.</p> <p>Post Darfield Earthquake Median Water Table Elevation</p> <p>Two median water table elevation surfaces developed from observation records for 967 shallow monitoring wells, modelled elevations of surface water along the river centre-lines and the coast. The slope of the surface was allowed to break perpendicular to rivers. Drawdown points were used to correct the model for local aberrations where the methodology produces a water table above the ground surface.</p> <p>A representative median water table elevation was calculated for each well. Only short term records (< 12 monthly records) were available for 310 wells, so surrogate medians were estimated using data from nearby wells with long-term records, to account for seasonal variation. One map of surface contours is provided for well observations with longer-term records (≥ 12 records) and the other contour map includes the surrogate short-term medians (< 12 records). The differences between the two surfaces are subtle, and in most places less than ± 0.5 m. Users need to decide which surface is more appropriate based on specific engineering requirements and match their own local site observations.</p> <p>These map layers and their background report were re-issued in May 2014 (version 2) and may be re-issued periodically to reflect ongoing groundwater monitoring within both existing wells and additional wells installed during the rebuilding of Christchurch City.</p> <p>85th and 15th Percentile Water Table Elevations</p> <p>Post-Darfield earthquake 85th and 15th percentile surfaces were created from the 85th and 15th percentile surface elevation observations at each site. The 85th percentile surface was created by calculating the difference between the 85th percentile and the median water level observed at each site, spatially interpolating these relative differences, then adding the interpolated differences to the median water table surface. The same method was used to create the 15th percentile surface. Expected groundwater variation at rivers and along the coastline were included in the calculations, based on observed surface water fluctuations. At drawdown points, 85th percentile values were set at ground level.</p> <p>These maps (new in version 2) provide context for the median water table surface, showing the variations of the water table in different parts of Christchurch City between 2010 and 2013. On</p>		

Map Layer and Description	Reference	Published
<p>average, the water table is below the 85th percentile surface for 85% of the observations at each monitoring well. Fifteen percent of observations should be below the 15th percentile surface.</p> <p>Post Darfield Earthquake Depth to Water Table – Median, 85th and 15th Percentile Elevations</p> <p>Maps of the depth of the median water table surface beneath a 25m-grid Digital Elevation Model (DEM) of the ground surface. This 25 m DEM was derived from 5m-grid DEMs, using the most recent, Feb 2012, augmented with additional extent from Sept 2011 (both in Map Layer CGD0500).</p> <p>These map layers and their background report were re-issued in May 2014 (Version 2) and may be re-issued periodically to reflect ongoing groundwater monitoring within both existing wells and additional wells installed during the rebuilding of Christchurch City.</p> <p>Median and 85th and 15th Percentile Grids for 1990-2010</p> <p>Fluctuations in groundwater between 1990 and 2010 were also considered best represented by the 85th percentile, median and 15th percentile elevations at 55 CCC and ECan shallow monitoring wells with long-term records. However, these three grid maps were independently interpolated using ordinary kriging. Surfaces for height above and depth below the median were then created from the interpolated surfaces. Between 1990 and 2010 there were inter-annual water table variations (around 2 m in the west and 1.2 m in the east) that were twice the scale of seasonal variations (around 1 m in the west, 0.5 m in the east). Natural fluctuations of groundwater occur at time-scales longer than post-Darfield Earthquake monitoring. The pre-Darfield Earthquake variations between 1990 and 2010 provide the best proxy of the likely scales of future water table fluctuations until more data is available.</p> <p>Confidence Index for All Records</p> <p>A qualitative confidence index (for all well records), that accounts for the density of monitoring wells and the duration of the recordings, indicating where there is a lower, medium or higher confidence in the median water table elevation map. Indicative precision reflects modelling experience and the local slope (hydraulic gradient) of the water table surface.</p> <p>References</p> <p>GNS Science (2013) Median water table elevation in Christchurch and surrounding area after the 4 September 2010 Darfield Earthquake, GNS Science Report 2013/01, March 2013, 66p and 8 Appendices (Superseded)</p> <p>van Ballegooy, S.; Cox, S. Port Hills Mass Movements and Surface Deformations	CGD5180	30 October 2014
<p>Description</p> <p>Relative hazard exposure categories for slope stability and surface deformations for the GNS Science mapped mass movements within the Port Hills, Christchurch.</p> <p>Methodology</p> <p>The two map layers were created by the Christchurch City Council from an interpretation of the mass movement maps provided within the GNS Science series of reports on Port Hills Slope Stability and the report on the findings from investigations into areas of significant ground damage (see references below).</p> <p>Final: Mass Movement Relative Hazard Exposure Categories</p> <p>Boundaries for Class I and II mass movement areas derived from the GNS Science report series on Port Hills Slope Stability and from the Class II and III mass movement areas identified by GNS Science based on field mapping. These final versions of the superseded Stage 1 areas (described below) are based on detailed studies that considered what could trigger a landslide, how big it could be, where and how the land is likely to move and, crucially, the level of risk to people.</p> <p>Stage 1: Mass Movement Surface Deformations</p> <p>Cracks related to subsurface movement at 34 potential mass movement areas associated with the Canterbury Earthquake sequence were collected during fieldwork between 4 December 2010 and January 2013. Cracks were mapped during site walkover inspections, with an approximate accuracy of ±5 m. Both cracking (extension) and localised uplift (compression) were recorded in the field at all sites where safe, owner agreed, access was possible. Where crack extension was observed, the relative vertical and horizontal displacement across the crack was estimated to the nearest 0.01 m. Crack widths often varied spatially so the estimates are those considered as most representative of the entire crack length. Only the spatial extents were recorded for compression features. Only cracking considered to be related to subsurface ground movement was recorded in order to minimise the contribution of features such as localised foundation damage etc within the mass movement deformations.</p> <p>Stage 1: (Superseded) Mass Movement Relative Hazard Exposure Categories</p> <p>Superseded boundaries for mass movement areas identified by GNS Science based on field mapping and the combined areal extent of tensions cracks, compression zones and other mass-movement landforms. The total displacement of these areas was estimated to be greater than 0.1 m relative to its surrounding land. The boundaries have an approximate accuracy of ±10 m and only encompass areas where ground movement was identified during the mapping (October 2012 to January 2013). They do not include areas where debris could run-out down-slope (where the hazard would be debris inundation) or areas where movement and cracking could retrogress up-slope from the currently mapped limits.</p> <p>Use limitations (all map layers)</p> <p>The Stage 1 dataset was prepared by the Institute of Geological and Nuclear Sciences Limited (GNS Science) exclusively for and under contract to Christchurch City Council as part of GNS Science Consultancy Report 2012/317. That report considers the risk associated with geological hazards. As there is always uncertainty inherent within the nature of natural events, GNS Science gives no warranties of any kind concerning its assessment and estimates, including accuracy, completeness,</p>

<p>timeliness or fitness for purpose and accepts no responsibility for any actions taken based on, or reliance placed on them by any person or organisation other than Christchurch City Council. GNS Science excludes to the full extent permitted by law any liability to any person or organisation other than Christchurch City Council for any loss, damage or expense, direct or indirect, and however caused, whether through negligence or otherwise, resulting from any person or organisation’s use of, or reliance on that report.</p> <p>The information shown on the map layers is based on field mapping (with accuracy as indicated above). Some viewing software provides terrain exaggeration and background imagery with unspecified location accuracy, which can affect the apparent positions of features.</p> <p>Only features apparent during the fieldwork were mapped and it should be noted that these features may change over time. For example, new cracks and areas of subsidence may appear and some cracks may disappear.</p> <p>The cracking data presented represents all the available data from the site at the time of collection, which may be subject to change through time. Additional data may be collected during the on-going studies so the source database may change in the future as data is added or updated. It is strongly recommended that any future studies undertaken in these areas should include both a detailed site inspection to ensure an adequate understanding of the ground conditions and an assessment of potential change since the database mapping.</p> <p>The mapped data should be used for information only.</p> <p>References</p> <p>C. <p>Description</p> <p><u>Network</u></p> <p>Railway Locations/Stations (Locations): Railway network locations, stopping points, stations or yards. Active location points functioning on the rail network. Does not represent the actual location of any physical structure.</p> <p>Bridges: Railway bridges, including structures over/under track. Represents centreline of bridge structure, represented as trace along MainLof track centreline (or centre of bridge for an overbridge)</p> <p>Railway tunnels (Tunnels): Represents centreline of tunnel structure, represented as trace along MainLof track centreline.</p> <p>KMPEGS: Kilometre posts or pegs depicting every full and half km (half km pegs are in Auckland and Wellington only). Represents Kilometre pegs located on Main Left track centreline, parallel to actual peg location</p> <p><u>Track Asset</u></p> <p>Track: All railway track, each segment representing an asset record in KiwiRails asset management database (Maximo), includes MainR, MainL, yards, sidings, loops, links and crossovers. Represents centreline of all track.</p> <p>New Zealand Geotechnical Database - Map Layer NZGD6010 – 19/02/2018</p>		

Map Layer Revision History

Revision	Layer	Description of Change
01 Oct 2012	All	Initial Release
28 Sep 2012	CGD5090	Initial Release of Cadastral Boundaries (2010)
	CGD5100	Initial Release of Cadastral Maps (Historical)
	CGD5110	Initial Release of Conditional PGA for Liquefaction Assessment
	CGD5120	Initial Release of Geological Maps
	CGD5140	Initial Release of Hazard Maps
	CGD5150	Initial Release of Topographic Maps
20 Nov 2012	CGD0400	Revised line colours to provide better distinction between crack widths and added note indicating intention of colouring.

	CGD0040 CGD0045	Added additional MASW investigation lines to both CBD and suburban data sets
	CGD0800	Updated the free surface elevations using additional well observation data
	CGD5010 CGD5020	Updated zones and categories to reflect changes announced on 12 November
	CGD5080	Initial Release of Geotechnical map layers
	CGD5120	Added the “Canterbury and Westland Geology – 1866” layer
	CGD5150	Corrected the source attribution for the map
11 Feb 2013	CGD0200	Add a new layer showing liquefaction interpreted from the 4 Sept 2010 aerial photography
	CGD0300	Add a new layer showing the liquefaction and lateral spreading observed on roads following the 22 Feb 2011 earthquake
	CGD0800	Updated the free surface elevations using additional well observation data
	CGD5110	All PGA layers corrected and layers added for additional significant earthquakes
19 Feb 2013	CGD5110	Revised 11 Feb 2013 corrections for 22 Feb 2011 earthquake
21 Feb 2013	CGD5140	Added Environment Canterbury “Liquefaction Assessment Area Map” and two accompanying liquefaction observations maps
07 Mar 2013	CGD5160	Initial release of GNS Science Median Water Table Elevations
30 May 2013	CGD0050 CGD0055 CGD0060	Initial release of Geotechnical Investigation Analysis tools for Liquefaction Evaluation of CPT Investigations, CPT Layer Analysis and Depth of Refusal and Soil Behaviour Type Index (Ic)
	CGD5170	Initial release of Ground Motion maps
31 Jan 2014	CGD5010 CGD5020	Updated maps of CERA Residential Zoning and MBIE Residential Foundation Technical Categories resulting from zoning changes announced on 5 Dec 2013
12 Jun 2014	CGD5160 CGD0800 CGD5180	Added Version 2 of GNS Science Median Water Table Elevation map layers Updated Event Specific Surface Elevations to use revised CGD5160 Medians Initial release of Port Hills Mass Movements and Surface Deformations
30 Oct 2014	CGD5140 CGD5180	Added the 2013 liquefaction susceptibility map for the Timaru District Updated Port Hills Mass Movement Exposure category areas
30 Jun 2015	CGD0020 CGD0050 CGD0500 CGD5110 CGD5170	Added Laboratory test data and reports for EQC site investigations Improved the Geotechnical Investigation Analysis tools for Liquefaction Additional colour banded ranges and contours added for Sept 2011 DEM Added PGA observations at GeoNet strong-motion recording stations Added GeoNet strong-motion station locations
22 Sep 2016	CGD0300 CGD5110	Added observations from 14 Feb 2016 earthquake Added PGA and standard deviation contours from 14 Feb 2016 earthquake
24 Oct 2017	CGD5120 CGD5120 CGD5120	Removed Canterbury and Westland Geology – 1866 (replaced by QMAP) Added GNS Geological Map of New Zealand (QMAP) Added GNS Christchurch Urban Geological Units
19 Feb 2018	NZGD6010	Added Kiwirail chainage to supplementary data
